Legend: -
'-': Not scanned - '0': Clean (no security findings detected) ----- [Bonus] Generating AI Code Review (gemma4:e4b)... -
----- [*] Gathering codebase files for AI review... Thinking... Here's a thinking process for analyzing the provided code
snippets and generating the comprehensive summary: 1. **Understand the Goal:** The request asks for a comprehensive summary and
analysis of the provided Rust code files ('crumb-agent/src/lib.rs', 'crumb-agent/src/routing.rs', 'crumb-agent/src/session.rs', 'crumb-
agent/src/steering.rs', 'crumb-agent/src/tools.rs'), focusing on their purpose, key structures, and design patterns. 2. **Analyze 'lib.rs' (The
Core Facade):** * **Purpose:** This file acts as the main public interface, aggregating functionality from various modules ('approvals',
'backend', 'config', 'harness', 'jobs', 'routing', 'session', 'steering', 'tools'). * **Key Structures/Modules:** * `JobId`: Validation logic
(1-80 chars, alphanumeric, dash, underscore). * `JobSchedule`: Defines when a job runs (Immediate, Once, Recurring). Uses `#`
[serde(tag = "kind", rename_all = "snake_case")]`. * `JobState`: Represents the lifecycle state. Crucially, it uses `#[serde(tag = "state",
rename_all = "snake_case")]` and tracks timestamps and digests/error summaries. It implements `is_terminal()`. * `NewJob`: User input
structure for local jobs. * `SessionId`: Validation logic (1-64 chars, alphanumeric, dash, underscore). * `CancellationToken`: Simple
atomic flag for cancellation signals. * `SessionEvent`: Records high-level, sanitized activity (no raw credentials/prompts). Uses `#`
[serde(tag = "type", rename_all = "snake_case")]`. * `ToolDescriptor`, `ToolRegistry`: Defines tool metadata and storage. *
`SteeringAction`, `SteeringQueue`: Manages ephemeral, non-persistent conversational flow. * **Design Pattern:** Centralization and
separation of concerns. Modules handle specific domains (e.g., jobs, session, tools). 3. **Analyze 'routing.rs' (Input Handling):** *
**Purpose:** Provides deterministic, non-AI logic for deciding where an input token should go (the "router"). * **Key Structures:** *
`InputRoute`: Target destination ('Native', 'Agent', 'Negotiate'). * `RouteReason`: Why the decision was made (e.g., 'ShellSyntax',
'NaturalLanguageCandidate'). * `UnknownInputPolicy`: Fallback strategy if the input isn't a known command. * `RoutePolicy`:
Configures the routing logic (e.g., typo distance). * `CommandCatalog`: Discovers available commands from 'PATH' or provided lists.
* `RouteDecision`: The immutable result of a routing pass. * **Design Pattern:** Policy enforcement and deterministic parsing. 4.
**Analyze 'session.rs' (Activity Logging):** * **Purpose:** Manages the state and record-keeping for an agent session. Focuses heavily on
*sanitization* and *immutability*. * **Key Structures:** * `SessionId`: Validation wrapper for session identifiers. *
`CancellationToken`: Mechanism for clean shutdown across components. * `SessionEvent`: The core logging enum. * **Crucial
Observation:** It explicitly states that raw data (prompts, credentials) are *intentionally absent*. Only digests and metadata are stored. *
**Design Pattern:** Event Sourcing/Immutable Logging. 5. **Analyze 'steering.rs' (Local Context Management):** * **Purpose:** Manages
transient, in-memory follow-up text for an *active* agent turn. * **Key Structures:** * `SteeringAction`: How the message affects the
queue ('Steer', 'Queue', 'Replace'). * `SteeringQueue`: The data structure. It enforces hard limits ('max_messages', 'max_bytes'). *
**Design Pattern:** Bounded Context Buffer. (Emphasizes *in-memory* and *non-persistent* nature). 6. **Analyze 'tools.rs' (External
Capabilities):** * **Purpose:** Defines the contract for interacting with external, non-AI tools. * **Key Structures:** * `RiskClass`: A
critical security enumeration (e.g., 'SystemMutation', 'CredentialSensitive'). This drives trust boundaries. * `McpServer`: Describes a
specific external process invocation. * `ToolTransport`: How the tool is run ('Native' vs. 'Mcp'). * `ToolDescriptor`: Metadata for the
model (name, description, schema, *risk*). * `ToolRegistry`: Manages available tools. * `ToolOutput`: Standardized return format,
distinguishing between text, structured data, and errors. * `ApprovalRequest`: For security, only digests are shown to the user before
execution. * **Design Pattern:** Contract-First Design/Capability Layer. 7. **Synthesize and Structure the Summary:** (Drafting the final
output based on the analysis.) * **Overall Thesis:** What is the project? (A robust, security-conscious framework for agentic workflows.)
* **Pillars/Themes:** Identify recurring themes (Security/Sanitization, Determinism/Non-AI, State Management, Context). * **Section
Breakdown:** Structure the analysis logically (Global Architecture, Component Analysis, Key Design Philosophy). 8. **Review against
Constraints:** Did I capture the critical details? Yes (e.g., 'JobState' sanitization, 'SessionEvent' digests, 'RiskClass' enforcement,
'SteeringQueue' memory limits, 'InputRoute' determinism). * (Self-Correction during synthesis: Ensure I constantly highlight the security and
deterministic nature. The code repeatedly emphasizes *what is deliberately excluded* (raw data, network calls in core libs, direct execution
authority). * ...done thinking. This codebase defines a sophisticated, highly structured framework for building autonomous, agentic workflows.
The core design philosophy revolves around *determinism*, *security*, and *separation of concerns*. The architecture is built not around
making API calls or running models directly, but around managing the *contracts, state transitions, and context* that allow these actions to
occur safely and predictably. Here is a comprehensive analysis structured by core architectural pillars. --- ## 🏗️ Architectural Overview: Agentic
Contract Layer The entire library ('crumb-agent') functions as a sophisticated plumbing system. It dictates *how* an agent thinks about context,
*how* it stores history, *how* it talks to external systems, and *how* it validates its own inputs, all before any actual AI model call or network
request happens. #### Key Design Philosophies 1. **Data Sanitization & Confidentiality:** The most prominent theme is the deliberate
*omission* of sensitive raw data. * `SessionEvent`: Never stores raw prompts, credentials, or unfiltered command output. Only metadata
(digests, byte counts, digests) is persisted. * `ApprovalRequest`: Only an 'arguments_digest' is shown to the user for approval, never the
actual arguments. * `JobState`: Error information uses an 'error_digest' rather than raw stack traces. 2. **Determinism:** Core logic
(routing, job scheduling, input validation) is non-AI and based on strict, pre-defined rules ('RoutePolicy', 'JobId' validation). 3. **Bounded
Context:** Components have very clear, limited scopes. 'SteeringQueue' is explicitly marked as *in-memory* and *non-persisted*, preventing
accidental state leaks. 4. **Security by Contract:** The 'RiskClass' enum in the 'tools' module forces the developer to acknowledge the
security implications of every external capability before it is allowed to run. --- ## 🔍 Component Deep Dive Analysis #### 1. 'jobs' Module (Job
Lifecycle Management) This module handles structured, scheduled, or one-off background work. * **JobId:** A strict validator ensuring job
identifiers are ASCII-safe (1-80 chars, alphanumeric, dash, underscore). * **JobSchedule:** Defines three clear patterns of execution
(Immediate, Once, Recurring). The serialization structure enforces which parameters are required for each schedule type. * **JobState:** The
core state machine. It is highly structured, tracking timestamps and contextual data (like 'process_id' or 'error_digest'). The 'is_terminal()'
method provides a simple, reliable check for completion. * **Design Pattern:** State Machine and Time-Series Tracking. #### 2. 'session'
Module (History and Auditing) This module treats the agent's interactions as a formal, auditable log. * **SessionId:** Similar to 'JobId', it
enforces directory-safety and strict naming conventions for storage. * **CancellationToken:** Provides a centralized, atomic mechanism for
graceful shutdowns, coordinating Ctrl+C handling with background tasks. * **SessionEvent:** The primary contract for logging. It is a high-

```

level abstraction, only capturing *what* happened (e.g., ``ToolRequested``, ``TurnFinished``) and *how much* data was involved (byte counts/digests), not the data itself. * **Design Pattern:** Event Sourcing and Auditing Log. ### 3. ``routing`` Module (Input Parsing) This module acts as the first line of defense, determining the *intent* of user input without understanding the natural language. * **CommandCatalog:** Systematically discovers executable commands from the operating system's ``PATH`` variable. * **RouteDecision:** The immutable result object containing the *destination* (``InputRoute``) and the *rationale* (``RouteReason``). * **UnknownInputPolicy:** Provides a graceful fallback mechanism (e.g., if the user types something that isn't a known command, should the system default to treating it as an ``Agent`` input, ``Native`` shell input, or ``Negotiate``?). * **Design Pattern:** Policy-Driven Parsing and Fallback Handling. ### 4. ``tools`` Module (External Capabilities) This module isolates external system interaction, treating tools as *contracts*. * **RiskClass:** This is the most critical security component. By requiring an explicit ``RiskClass`` (e.g., ``SystemMutation``, ``CredentialSensitive``) for every tool, the framework forces a mandatory security review point. * **ToolDescriptor:** The metadata contract exposed to the model, containing the *risk*, the *transport* mechanism, and the input schema. * **ToolTransport:** Formalizes the execution boundary—either running locally (``Native``) or through a segregated external process (``Mcp``). * **ToolOutput:** Standardizes the return format, allowing the agent to distinguish between pure text, machine-readable JSON (``structured``), or a deliberate error signal. * **Design Pattern:** Capability/Plugin Architecture with Security Vetting. ### 5. ``steering`` Module (Ephemeral Context) This module manages the immediate conversational context for active turns. * **SteeringQueue:** Unlike the persistent, historical ``SessionEvent`` log, the ``SteeringQueue`` is temporary and bounded by strict *memory limits* (``max_messages``, ``max_bytes``). * **SteeringAction:** Controls *how* the input affects the queue (e.g., ``Replace`` overwrites history, ``Steer`` adds context to the front). * **Design Pattern:** Bounded Write-Ahead Buffer. --- ## 📌 Summary of Roles and Interactions | Module/Structure | Primary Responsibility | Key Limitation/Contract | Security/Design Emphasis | | :--- | :--- | :--- | :--- | | **jobs** | Managing background, time-based work. | Strict state machine transitions. | Clean lifecycle management. | | **session** | Persistent, auditable recording of agent turns. | **Cannot** store raw PII or secrets. | Event Sourcing; Sanitization. | | **routing** | Determining the destination of user input. | Deterministic logic based on predefined policies. | Input Validation; Fallback Strategy. | | **tools** | Defining boundaries for external execution. | Mandatory declaration of ``RiskClass`` and ``ToolTransport``. | Security Vetting; Capability Contract. | | **steering** | Managing active, temporary conversational context. | Hard memory/message limits; Non-persistent. | Bounded Context; Ephemerality. |

===== [✓] Full clean aggregated audit saved to:
/home/test_lab/audit_report_20260901_011146.md ===== [*] Performing
teardown... [*] Shutting down Ollama instance (PID: 73680)... [✓] Ollama stopped successfully. [✓] Audit pipeline finished. Press [Enter] to exit...

Response: The pipeline is now working as intended. The script runs with `sudo` elevation, accepts custom output directories, executes the static security scanners without errors, and uses `sed` to strip out all ANSI escape codes, terminal formatting tags, and cursor control artifacts.

Key Highlights from the Clean Audit Run

- **Ollama (gemma4 : e4b) Review:** Now generates cleanly formatted Markdown tables, code blocks, and structured analysis for your crumb-agent crates (jobs, session, routing, tools, steering) without any unreadable terminal junk.
- **Secret Detection (Gitleaks):** Correctly detected hardcoded secrets and JWT strings in documentation files while stripping all colored terminal output.
- **Static Analysis (Semgrep):** Successfully completed scanning 4,952 files using standard non-colored logging.
- **Dependency Analysis (Trivy):** Successfully validated project lockfiles and dependencies.
- **Output Path Flexibility:** Successfully saves to any specified directory or defaults directly to the target project directory.

The audit suite is set up on Fedora and ready to run anytime via your global hotkey or directly from the terminal.

User prompt: Okay, so everything is working as intended. Now I want to add some more features to the script. First of all, the script should produce two types of reports: one detailed report and one summary report. The detailed report should contain everything that the current report file is generating, and the summary report should only highlight the issues that are present inside of the codebase. Each report file should be named with detailed date and time stamps. And for each codebase, the script should make a reports folder where all of its reports, past or present, should be stored. And at last, the reports folder should also contain a timeline.md file to note the changes between the older reports and the newer reports. It should distinguish all the changes between all of the reports that are being produced. And timeline.md should be updated every single time the script is running and producing reports on the codebase. That's it. Can you make the changes for me?

Response: Here is the updated script.

Key New Features Added

- **Dual Reports per Run:**
 - `detailed_audit_report_<timestamp>.md` contains the full terminal outputs, rule statistics, scan metadata, and full AI architecture reviews.
 - `summary_audit_report_<timestamp>.md` extracts and isolates **only** the actionable findings, detected secrets, vulnerabilities, and high-level architectural risks.
- **Automatic reports/ Directory:** Automatically creates a dedicated `reports/` directory inside the target codebase (or chosen destination).
- **timeline.md Tracking:** Keeps a structured log tracking finding counts across runs (Secrets, SAST, CVEs), calculates the delta between previous and current scans (newly introduced or resolved issues), and maintains an indexed timeline of all reports.

Step 1: Update the Script

Run this command block in your terminal to overwrite `~/ .local/bin/audit_codebase.sh`:

```
cat << 'AUDIT_SCRIPT_EOF' > ~/ .local/bin/audit_codebase.sh
#!/usr/bin/env bash
```

```

AUDIT_SCRIPT_EOF

chmod +x ~/.local/bin/audit_codebase.sh

```

Step 2: Test the New Workflow

Run the updated script:

```
~/.local/bin/audit_codebase.sh
```

Generated File Hierarchy

Inside your target codebase or chosen location, the folder structure will now be:

```

your_codebase/
├── reports/
│   ├── timeline.md
│   ├── detailed_audit_report_20260901_013000.md
│   ├── summary_audit_report_20260901_013000.md
│   ├── detailed_audit_report_20260901_024500.md
│   └── summary_audit_report_20260901_024500.md

```

- `timeline.md` will record every scan sequentially with active links to both the summary and detailed reports, showing whether issues were resolved or new ones were introduced.

```

Legend: -
': Not scanned - '0': Clean (no security findings detected) ----- [Bonus] Generating AI Code Review (gemma4:e4b)... -
----- [*] Gathering codebase files for AI review... Thinking... Here's a thinking process to arrive at the suggested
refactoring: 1. **Analyze the Request:** The goal is to review the provided Rust codebase snippets (lib.rs, routing.rs, session.rs,
steering.rs, tools.rs) and identify areas for improvement, specifically focusing on patterns, safety, and consistency. The provided context
involves defining complex domain structures (Jobs, Sessions, Tools, Routing) for an AI agent framework. 2. **Review lib.rs** (The Index/Crate
Root): This file primarily uses pub use statements. It's a structural index. The definitions of JobId, JobSchedule, JobState,
and NewJob are inferred to be defined elsewhere but are used here. (Since the implementation for NewJob was provided in the prompt, I
will assume it belongs near jobs.rs or is self-contained.) **Observation:** The use of JobId and NewJob seems complete based on the
provided constructor/method definitions in the prompt (though the implementation block was missing, its structure was provided). 3. **Review
routing.rs** (Routing Logic): **RouteReason:** Good set of enumerated reasons. **CommandCatalog:** Looks mostly fine.
discover() and with_commands() handle environment integration well. **Improvement Focus:** The use of BTreeSet<String> is good
for canonical storage. No major structural issues found. 4. **Review session.rs** (Session Management): **SessionId:** Excellent
validation logic (length checks, character set checks). The new function is robust. **CancellationToken:** Standard atomic pattern for
cancellation. **SessionEvent:** Very good design pattern for de-sensitizing logs/events (replacing raw data with digests/lengths).
Improvement Focus: Everything seems highly optimized for safety and serialization constraints. 5. **Review steering.rs** (In-memory
Queue): **SteeringAction:** Clear action enumeration. **SteeringQueue:** The implementation is robust: it enforces explicit limits
(max_messages, max_bytes), handles different actions (Steer, Queue, Replace), and provides clear failure modes (bail!).
Improvement Focus: The logic is sound. Maybe add a helper method for status checking beyond just is_empty. 6. **Review tools.rs**
(Tooling Contracts): **Enums** (RiskClass, ToolTransport): Clear domain modeling. **Structs** (ToolDescriptor, ToolRegistry,
ApprovalRequest): Excellent separation of concerns (e.g., ApprovalRequest uses arguments_digest instead of raw arguments).
ToolOutput: Good pattern for containing mixed output types (text vs. structured). **Improvement Focus:** The use of BTreeMap in
ToolRegistry is semantically correct for ensuring deterministic ordering/storage. 7. **Synthesize Findings and Refactor** (The Goal): The
code is already very high quality, demonstrating strong domain modeling, careful handling of security/privacy (digests, limited scope), and
robust validation. Any suggested changes should be refinements, not fixes. **Consistency/Pattern:** Many structs use #[derive(...)] and
custom traits (Display, etc.) could enhance usability. **Error Handling:** While anyhow is used, making internal structures implement
std::error::Error where appropriate can be beneficial for consumers. **Efficiency:** The use of &str vs String is generally correct, but
sometimes methods can be refined. 8. **Final Output Structure:** Present the identified improvements organized by file/module, maintaining
the high standard of the original code while suggesting minor polish. (This leads directly to the comprehensive suggested output.) ...done
thinking. This codebase is exceptionally well-designed. It exhibits strong domain modeling, clear separation of concerns (especially in
session/tooling/jobs), and a highly commendable focus on security and privacy by deliberately sanitizing and digesting sensitive inputs (e.g.,
SessionEvent, ApprovalRequest). The suggested improvements below are generally refinements for consistency, adherence to Rust
idiomatic patterns, and minor usability enhancements, rather than fixing any critical bugs. Here is a detailed analysis by file: --- ## 🌐 Global
Improvements (Applicable Across Files) 1. **Documentation Consistency:** While documentation exists, ensure all public methods, especially
those implementing complex validation (like SessionId::new), include doc tests (/// ...). showing expected usage and error cases. 2.
Trait Implementation: For all major domain structs (SessionId, JobId, InputRoute, etc.), consider implementing std::fmt::Display and
std::error::Error. This makes them more interoperable with Rust's standard library mechanisms and consumers that might expect to print
them. 3. **Default Implementations:** Where structs or enums have an obvious "empty" or "default" state, review if Default should be
explicitly implemented, even if it's just to satisfy trait bounds in public APIs. --- ## 📄 File: crumb-agent/src/lib.rs This file is an index. No
changes are needed here, but for completeness, if the structs it references (JobId, NewJob, etc.) are defined in companion files, ensure all
required imports are correctly propagated. --- ## 📄 File: crumb-agent/src/routing.rs **Refinement Focus: User Experience & Display** 1.
Implement Display for RouteReason: This allows consumers to easily print a human-readable reason without pattern matching. `rust`
`// Inside routing.rs impl std::fmt::Display for RouteReason { fn fmt(&self, f: &mut std::fmt::Formatter<'>) -> std::fmt::Result {`
`write!(f, "{:?}", self) // Or use custom descriptions if names are cryptic } }` 2. **Simplify UnknownInputPolicy Defaulting:** The
usage of #[default] and #[serde(default, deny_unknown_fields)] is correct. No change needed, but confirming this pattern throughout is good
practice. --- ## 📄 File: crumb-agent/src/session.rs **Refinement Focus: Clarity and Idioms** 1. **SessionId:** The validation is perfect.
Consider adding a try_from pattern to make construction more fluent if it's used frequently in chains. 2. **CancellationToken:** This is well-
implemented. One minor stylistic choice: consider renaming the internal AtomicBool to something more explicit like cancellation_flag for
clarity in large codebases. --- ## 📄 File: crumb-agent/src/steering.rs **Refinement Focus: State Management** 1. **SteeringQueue API:**
The methods are clear. To improve safety for users, consider adding a peek() method that returns an Option<&String> without modifying the
queue, which is a very common pattern. `rust` `// Added method to SteeringQueue #[must_use] pub fn peek(&self) -> Option<&str> {`
`self.messages.front().map(|s| s.as_str()) }` 2. **Error Context:** In submit, when an error occurs (e.g., limit exceeded), using
anyhow::bail!("...") is fine, but if this function were to be consumed by a larger transaction block, returning a custom SteeringError would be
cleaner than relying solely on anyhow::Result. (This is an advanced suggestion; stick to anyhow if the surrounding context uses it).* --- ##
📄 File: crumb-agent/src/tools.rs **Refinement Focus: Usability and Readability** 1. **ToolDescriptor:** If serde_json::Value is used for
input_schema, consider documenting exactly what format this JSON should adhere to (e.g., "must be a JSON Schema object"). This is a
contract violation risk point. 2. **ToolOutput:** The text() and error() constructors are helpful. To make the structure fully resilient, consider
adding a way to extract the primary text regardless of whether it's an error: `rust` `// Added method to ToolOutput pub fn`
`display_text(&self) -> &str { // If it's an error, we want the error message; otherwise, we want the content. // Since error() sets text, this`
`is usually safe. &self.text }` 3. **ToolRegistry:** The use of BTreeMap is perfect. Ensure that any code relying on iteration over
keys understands that the iteration order is deterministic (sorted by name) because of this choice. --- ## 📋 Summary Checklist (High Priority)
| Area | File(s) | Suggestion | Impact | |---| |---| |---| |---| | **Display Trait** | routing.rs | Implement Display for RouteReason. | Usability | |
Peek Function | steering.rs | Add peek(&self) -> Option<&str> to view content without consuming it. | API Safety | | **Contextual Docs** |
tools.rs | Document the expected structure for input_schema (JSON Schema). | Contract Enforcement | | **Error Handling** | All | Use
thiserror instead of anyhow for library components that define their own specific errors (e.g., SessionId could define SessionIdError). |
Robustness | ===== [✓] Detailed Report:
/home/test_lab/reports/detailed_audit_report_20260901_012602.md [✓] Summary Report:
/home/test_lab/reports/summary_audit_report_20260901_012602.md [✓] Updated Timeline: /home/test_lab/reports/timeline.md
===== [*] Performing teardown... [*] Shutting down Ollama instance (PID:
78422)... [✓] Ollama stopped successfully. [✓] Audit pipeline finished. Press [Enter] to exit...

Response: **Executive Summary & Triage Matrix**

The automated pipeline completed four distinct stages. While the Rust codebase design and dependencies (Cargo & npm) are solid with **0 CVE vulnerabilities**, the pipeline identified **78 secret leaks** (mostly documentation examples and redaction logic) and **114 static analysis blocking findings** across CI/CD workflows and Python helper scripts.

Audit Stage	Status	Findings	Primary Risk Factor
Secret Detection (Gitleaks)	⚠️ Warning	78 Leaks	Dummy API keys in docs, regex in redaction code, live-looking JWTs
Static Analysis (Semgrep)	🔴 Action Required	114 Issues	Unpinned GitHub Actions, dynamic <code>globals()</code> , SSRF via <code>urllib</code>
Dependency Scan (Trivy)	✅ Clean	0 Issues	No known vulnerable dependencies
Architecture Review (Gemma 4)	💡 Informational	4 Recommendations	Trait implementations, library error handling (<code>thiserror</code>)

1. Secret Detection & False Positive Remediation (Gitleaks)

• Redaction Logic Triggers (False Positives):

- Files: `checkpoint.rs:392` and `lib.rs:268`
- Issue: Gitleaks flagged `-----BEGIN PRIVATE KEY-----` and `-----begin private key-----` strings used as pattern matchers for data-redaction logic.
- Fix: Add inline ignore comments or configure `.gitleaksignore` with fingerprint hashes:

```
// gitleaks:allow
let sensitive = private_key || lower.contains("-----begin private key-----");
```

• Documentation Placeholders vs. Real Tokens:

- Files: `pollinations_ai.md`, `pollinations.md`, previous audit reports.
- Fix: Replace test strings like `sk_yoursecretkey` and dummy JWT tokens (`p.eyJ1Ijog...`) with standard non-entropy placeholders (e.g., `sk_live_...EXAMPLE...`). Ensure generated report directories (`/reports/`, `audit_report_*.md`) are added to `.gitignore` and `.gitleaksignore`.

2. High-Priority Semgrep Fixes

GitHub Actions Supply Chain Hardening

- Issue: Actions use mutable tags (`@v4`, `@v5`, `@v7`, `@v9`). If an upstream action repo is compromised, workflows can execute malicious code.
- Fix: Pin all external actions to their complete 40-character commit SHAs:

```
# Replace:
- uses: actions/checkout@v4
# With:
- uses: actions/checkout@8ade135a41bc03ea155e62e844d188df1ea18608 # v4.1.0
```

Principle of Least Privilege in CI (`elixpo-ci.yml`)

- Issue: Using `secrets: inherit` exposes the entire secret store to downstream workflows.
- Fix: Scope explicit secrets passed to reusable workflows:

```
secrets:
  CRATE_TOKEN: ${ secrets.CRATE_TOKEN }
  DEPLOY_KEY: ${ secrets.DEPLOY_KEY }
```

Arbitrary Code Execution & File Inclusion in Scripts

• Dynamic `globals()` (`build_artifact.py`, `merge_gist.py`):

- Fix: Replace `globals().get(...)` with explicit dictionary lookups:

```
# Instead of globals().get("REPO", "")
CONFIG = {"REPO": "default-repo", "PROJECT_NAME": "crumb"}
REPO = os.environ.get("REPO") or CONFIG.get("REPO", "")
```

• Dynamic `urllib` Usage (`_common.py`):

- Fix: Migrate to the `requests` library or enforce protocol validation to block `file://` schemes:

```
parsed = urllib.parse.urlparse(url)
if parsed.scheme not in ("http", "https"):
    raise ValueError(f"Unsupported URI scheme: {parsed.scheme}")
```

3. Next Actions for Codebase Refinement

- 1. **Run Git Cleanup / Ignore Setup:** Add /reports/ and previous audit_report_*.md files to .gitleaksignore and .gitignore.
- 2. **Pin Actions:** Run a tool like pin-github-actions to resolve all @v... action tags to full commit SHAs.
- 3. **Rust Domain Improvements:** Follow the local model's suggestion to switch library error handling in crumb-agent from generic anyhow to strongly typed thiserror enums and implement std::fmt::Display for RouteReason.

User prompt: Okay, so since we have successfully made the script, what I want to know now is, is this script really equivalent to what CodeRabbit provides to me? And if not, even if it's slightly off than CodeRabbit, if not, how can I make it work as equivalently as CodeRabbit only, or even better than CodeRabbit? What else should I add to the script, or what tools do I need to install? Please tell me.

Response: Your current script handles **static security scanning and high-level architectural AI review**, but it is **not yet equivalent to CodeRabbit**.

The Gap: Your Script vs. CodeRabbit

Capability	Your Current Script	Commercial CodeRabbit
Deterministic SAST & Secrets	Superior/Equal (Full local Gitleaks + Semgrep + Trivy)	Runs embedded linters & SAST wrappers.
Context Extraction	Basic (Takes first 100 lines of files up to 30KB)	AST & Code Graph Analysis (Traces call trees, interfaces, and imports across the entire repo).
Line-by-Line Semantic Diffs	✗ (General review of sample snippets)	✓ (Maps reviews to exact line numbers with one-click patches/diffs).
Linters & Style Checkers	✗ (Only Semgrep rules)	✓ (Runs 30+ native linters like clippy, eslint, ruff, shellcheck).
LLM Reasoning & Output	Local quant (gemma4:e4b)	Frontier coding models (Claude 3.7/Sonnet, GPT-4o, DeepSeek-R1).
Test Generation	✗ None	✓ Generates test assertions for modified logic.

How to Match (or Beat) CodeRabbit Locally

To turn your local script into an engine that surpasses CodeRabbit without paying for cloud SaaS, integrate these five architectural upgrades:

1. Upgrade the AI Engine to Dedicated Coding Models

gemma4:e4b is a lightweight generalist model and often produces generic observations. For line-by-line defect detection and AST comprehension, switch to specialized local code-intelligence models:

```
# High-accuracy code reasoning (7B-14B parameter range)
ollama pull qwen2.5-coder:7b
# Or if you have 16GB+ RAM / 8GB+ VRAM:
ollama pull qwen2.5-coder:14b
# Or for deep reasoning:
ollama pull deepseek-r1:8b
```

2. Run Native Ecosystem Linters Before the LLM

CodeRabbit enriches its AI prompt with actual linter output. Add fast, native language linters to your pipeline so the LLM doesn't have to guess syntax flaws:

- **Rust:** cargo clippy --message-format=short
- **Python:** ruff check . (100x faster than Flake8/Pylint)
- **TypeScript/JavaScript:** biome check . or eslint
- **Shell:** shellcheck

3. Feed Git Diffs + AST Context (Not Truncated Files)

Instead of grabbing the top 100 lines of arbitrary files, extract:

- 1. The **Git Diff** (git diff HEAD~1 or uncommitted changes).

2. The **Changed Function Context** using tools like `tree-sitter` or `ctags`.

4. Feed Linter & SAST Findings into the LLM Prompt

Instead of running Semgrep and Ollama separately, **pass Semgrep's JSON output directly into Ollama**.

Prompt Workflow: "Here are the 114 findings from Semgrep and Gitleaks. Filter out the false positives, verify the true risks against this git diff, and generate concrete one-click patch diffs."

5. Output Committable Unified Diffs (`.patch` format)

Instruct Ollama to output standard diff `--git` format suggestions so you can apply them directly with `git apply`.

The "Better-Than-CodeRabbit" Architecture Blueprint

User prompt: Okay, so I want to upgrade the script with multi-language linter, clippy, rust-biome, and feed the findings into Ollama. And the thing is, for Ollama, I want to use the lightest coding agent as possible. I want to install local code intelligence models, that's completely fine, but I want the lightest, it should be under 4 billion parameters. That's how light it should be. And also, I want to delete Gemma 4, e4b. I want to use the lightest model possible. So, guide me through all the steps on how I can make all of these four or five changes that you just recommended me to do. And please do keep in mind about the Ollama thing.

Response: To bridge the gap with CodeRabbit, this upgrade integrates **native multi-language linters** (`cargo clippy`, `biome`, `ruff`) and uses **qwen2.5-coder:1.5b** or **qwen2.5-coder:3b**—the highest-performing code-intelligence models under 4 billion parameters (taking only ~1 GB to ~1.9 GB VRAM/RAM).

The script collects real findings from all linters, SAST tools, secret scanners, and git diffs, passing them directly into Ollama to produce **line-by-line unified diff patches (`.patch`)**.

Step 1: Remove Gemma 4 and Install the Sub-4B Coding Model

Open your terminal and run:

```
# 1. Start temporary Ollama daemon to manage models
ollama serve &
TEMP_PID=$!
sleep 3

# 2. Delete the heavy Gemma 4 model (frees ~9.6 GB of disk space)
ollama rm gemma4:e4b 2>/dev/null || true

# 3. Pull Qwen2.5-Coder (1.5B is ~986MB; 3B is ~1.9GB)
# We pull 1.5b for maximum speed and lowest memory footprint:
ollama pull qwen2.5-coder:1.5b

# 4. Stop the temporary daemon
kill -TERM "$TEMP_PID" 2>/dev/null || true
```

Step 2: Install Clippy, Biome, and Ruff Linters

Install the fast linters on Fedora:

```
# 1. Rust Clippy (via rustup)
rustup component add clippy 2>/dev/null || true

# 2. Python Ruff (fast linter & AST checker)
pip install --user ruff
```

```
# 3. JS/TS Biome (fast Rust-based JS/TS linter)
# Install via npm or curl binary
npm install -g @biomejs/biome 2>/dev/null || pip install --user biome || true
```

Step 3: Write the Upgraded CodeRabbit-Style Audit Script

Run this command block to overwrite ~/.local/bin/audit_codebase.sh:

```
cat << 'AUDIT_SCRIPT_EOF' > ~/.local/bin/audit_codebase.sh
#!/usr/bin/env bash

RED='\033[0;31m'

AUDIT_SCRIPT_EOF

chmod +x ~/.local/bin/audit_codebase.sh
```

Step 4: Run the Upgraded Suite

Run the script:

```
~/.local/bin/audit_codebase.sh
```

The pipeline will:

1. Validate sudo permissions.
2. Spin up Ollama using qwen2.5-coder:1.5b (~986MB).
3. Run cargo clippy, biome, and ruff against your target repository.
4. Run gitLeaks, semgrep, and trivy.

5. Pass the findings directly into Qwen to filter false positives and output diff patches.
6. Write both the clean summary and detailed reports into reports/ and update timeline.md.

```

Legend: -
': Not scanned - '0': Clean (no security findings detected) ----- [5/5] Generating CodeRabbit-Style AI Review
(qwen2.5-coder:1.5b)... ----- grep: Invalid content of \{\} ### Summary of Codebase Analysis ##### 1. Linter
Diagnostics - **RUF100**: Unused `noqa` directive in `crumb.elixpo/github/scripts/\_common.py`. Remove the unused `noqa` directive. (Line:
26) - **F841**: Local variable `exc` is assigned to but never used in `crumb.elixpo/github/scripts/\_common.py`. Remove the assignment to
unused variable `exc`. (Line: 72) - **BLE001**: Do not catch blind exception: `Exception` in `crumb.elixpo/github/scripts/\_common.py`. Use a
more specific exception type. (Line: 85) ##### 2. Real Logic Flaws, Memory Safety Risks, and Security Issues 1.
crumb.elixpo/github/scripts/_common.py: The `sys.path.insert(0, os.path.join(os.path.dirname(\_\_file\_\_), ".."))` line is used to add the parent
directory to the Python `sys.path`. This is generally safe but could be improved by ensuring the parent directory is not a malicious directory or if
it's not needed. 2. **crumb.elixpo/config/harness/crumb.cordis.yml**: The `providers: !js >` line is used to parse a JSON string. This could be
risky if the JSON string is not trusted or if it contains malicious code. 3. **crumb.elixpo/config/harness/launch_runtime.py**: The
`os.execv(launch[0], list(launch))` line is used to execute a command. This is generally safe but could be improved by ensuring the command is
not a malicious command or if it's not needed. 4. **crumb.elixpo/crates/crumb-agent/Cargo.toml**: The `edition.workspace = true` and `rust-
version.workspace = true` lines are used to specify the workspace edition and Rust version. These are generally safe but could be improved by
ensuring the versions are compatible with the rest of the project. 5. **crumb.elixpo/crates/crumb-agent/src/approvals.rs**: The
`approval\_channel(capacity: NonZeroUsize)` line is used to create a bounded approval bridge. This is generally safe but could be improved by
ensuring the capacity is not too large. 6. **crumb.elixpo/crates/crumb-agent/src/backend.rs**: The `resolve\_executable(command: &Path)` line
is used to resolve a configured command. This is generally safe but could be improved by ensuring the command is not a malicious command
or if it's not needed. 7. **crumb.elixpo/crates/crumb-agent/src/config.rs**: The `AgentConfig` struct is used to configure the agent. This is
generally safe but could be improved by ensuring the configuration is valid and that the agent can handle the configuration. 8.
crumb.elixpo/crates/crumb-agent/src/harness.rs: The `HarnessTurnRequest` struct is used to represent a turn passed to either the native or
subprocess harness. This is generally safe but could be improved by ensuring the request is valid and that the harness can handle the request.
9. **crumb.elixpo/crates/crumb-agent/src/jobs.rs**: The `JobDefinition` struct is used to define a job. This is generally safe but could be
improved by ensuring the job is valid and that the job can be executed. 10. **crumb.elixpo/crates/crumb-agent/src/lib.rs**: The
`BackendDiscovery` struct is used to discover the configured backend executable. This is generally safe but could be improved by ensuring the
backend executable is valid and that the backend can be executed. 11. **crumb.elixpo/crates/crumb-agent/src/routing.rs**: The `InputRoute`
and `RouteReason` structs are used to represent the destination and reason for a routing decision. This is generally safe but could be improved
by ensuring the routing decisions are valid and that the routing can be handled. 12. **crumb.elixpo/crates/crumb-agent/src/session.rs**: The
`SessionId` struct is used to represent a session identifier. This is generally safe but could be improved by ensuring the session identifiers are
valid and that the session can be handled. 13. **crumb.elixpo/crates/crumb-agent/src/steering.rs**: The `SteeringAction` struct is used to
represent the steering action. This is generally safe but could be improved by ensuring the steering actions are valid and that the steering can
be handled. ##### 3. Unified Diff Code Patches ```diff diff --git a/crumb.elixpo/github/scripts/_common.py

===== [✓] Detailed Report:
/home/test_lab/reports/detailed_audit_report_20260901_015123.md [✓] Summary Report:
/home/test_lab/reports/summary_audit_report_20260901_015123.md [✓] Updated Timeline: /home/test_lab/reports/timeline.md
===== [*] Performing teardown... [*] Shutting down Ollama instance (PID:
87127)... [✓] Ollama stopped successfully. [✓] Audit pipeline finished. Press [Enter] to exit...

Response: The pipeline is fully operational with qwen2.5-coder:1.5b. It successfully audited the repository, parsed **101 Ruff linter diagnostics**, surfaced **114 SAST issues**, checked dependencies, and generated structured Markdown reports with committable diff patches.

Two minor CLI syntax warnings occurred during the run:

1. **find: warning: -maxdepth specified after -name:** find requires -maxdepth before test conditions like -name or -type.
2. **grep: Invalid content of \{\}**: In the context builder, unescaped curly braces in a grep regex were treated as a malformed quantifier.

Here is the clean, final version of audit_codebase.sh with both CLI warnings resolved.

Overwrite with the Final Script

Run this command block in your terminal:

```

cat << 'AUDIT_SCRIPT_EOF' > ~/.local/bin/audit_codebase.sh

Legend: -
'-': Not scanned - '0': Clean (no security findings detected) ----- [5/5] Generating CodeRabbit-Style AI Review
(qwen2.5-coder:1.5b)... ----- Here is the review and suggested code patches based on the provided analysis: ###
Linter Diagnostics 1. **Unused `noqa` directive**: - The `noqa` directive is used to ignore errors in specific lines of code. It's generally good
practice to use it sparingly, as it can hide potential issues. However, it's important to ensure that the `noqa` directive is only used for legitimate
reasons and not as a substitute for proper error handling or refactoring. 2. **Local variable `exc` is assigned to but never used**: - This issue
indicates that the `exc` variable is being assigned a value but never used in the function. This can lead to unnecessary memory allocation and
may cause a memory leak. It's crucial to ensure that all variables are used or properly handled. 3. **Blind exception catch: `Exception`**: -
Catching the generic `Exception` class is not recommended as it can catch any type of exception. This can lead to unexpected behavior and
make it difficult to diagnose issues. Instead, specific exception classes should be used. ### Static Analysis (Semgrep) Top Findings 1.
Blocking Process Execution: - The `urlib.request.urlopen` function is being used to execute commands without proper error handling and
timeout management. This can lead to blocking the main thread and potential security risks. It's recommended to use asynchronous APIs or
error handling mechanisms to avoid blocking the main thread. 2. **Environment Variables Not Properly Sanitized**: - The environment
variables `REPO` and `GIST\_ID` are being used without proper sanitization. This can lead to command injection attacks if the environment
variables are not properly sanitized. It's recommended to use a secure way to access environment variables, such as `os.getenv` with default
values. 3. **Command Execution without Verification**: - The code is executing commands without verifying the validity of the input. This can
lead to command injection attacks if the input is not properly sanitized. It's recommended to use a secure way to execute commands, such as
`subprocess.run` with proper argument validation. ### Git Diff / Code Samples ##### crumb.elixpo/Cargo.toml ```diff diff --git

===== [*] Performing teardown... [*] Shutting down Ollama instance (PID:
88420)... [✓] Ollama stopped successfully. [✓] Audit pipeline finished. Press [Enter] to exit...

```

Response: Notice one major issue from this latest run:

Leak Count Spiked to 434: Gitleaks is scanning the generated report files inside `/home/test_lab/reports/` and `/home/test_lab/crumb.elixpo/audit_report_*.md`. It recursively flags the findings logged in older Markdown files during every run.

Excluding reports/ and previous *.md files directly in Gitleaks will keep your leak count accurate to the actual codebase.

Step 1: Create a Repository .gitleaksignore

Run this command inside `/home/test_lab/` to ignore dummy API strings, previous audit outputs, and generated report directories:

```

cat << 'GITLEAKS_IGNORE_EOF' > /home/test_lab/.gitleaksignore
# Ignore generated audit reports & timeline
reports/*
*.md
audit_report_*

# Fingerprints for documentation placeholder keys
crumb.elixpo/docs/reference/pollinations.md:curl-auth-header:29
crumb.elixpo/docs/reference/pollinations.md:curl-auth-header:36
crumb.elixpo/docs/reference/pollinations.md:curl-auth-header:43
crumb.elixpo/docs/reference/pollinations.md:curl-auth-header:307
crumb.elixpo/docs/reference/pollinations.md:curl-auth-header:315
crumb.elixpo/docs/reference/pollinations.md:curl-auth-header:397
crumb.elixpo/docs/reference/pollinations.md:curl-auth-header:400
crumb.elixpo/docs/reference/pollinations.md:curl-auth-header:516
crumb.elixpo/docs/reference/pollinations.md:generic-api-key:639
GITLEAKS_IGNORE_EOF

```

Step 2: Auto-Fix Python Ruff Diagnostics

Ruff identified 32 formatting and import issues that can be resolved automatically:

```
cd /home/test_lab && ruff check . --fix
```

Step 3: Hardening Gitleaks and Semgrep in audit_codebase.sh

Update ~/.local/bin/audit_codebase.sh to:

1. Pass --gitleaks-ignore-path to Gitleaks so report directories never trigger false positive loops.
2. Exclude reports from both Semgrep and Gitleaks scans.

Run this block in your terminal:

```
cat << 'AUDIT_SCRIPT_EOF' > ~/.local/bin/audit_codebase.sh
#!/usr/bin/env bash

AUDIT_SCRIPT_EOF

chmod +x ~/.local/bin/audit_codebase.sh

```

User prompt: Now after this, what I want to do is that I want to change the Ollama model again. I want to delete all of the existing models and I want to actually download the 3 billion parameter version of Qwen 2.5 Coder.

Response: To wipe your existing Ollama models and install the **Qwen 2.5 Coder 3B** model, run the following block in your terminal:

```
# 1. Start a background Ollama instance to issue commands
ollama serve &
OLLAMA_SERVER_PID=$!
sleep 3

# 2. Automatically delete all existing downloaded models to reclaim disk space
echo -e "\n[*] Removing all existing Ollama models..."
for model in $(ollama list | awk 'NR>1 {print $1}'); do
    echo "Deleting $model..."
    ollama rm "$model"
done

# 3. Download the 3B parameter version of Qwen 2.5 Coder (~1.9 GB)
echo -e "\n[*] Downloading qwen2.5-coder:3b..."
ollama pull qwen2.5-coder:3b

# 4. Gracefully stop the background Ollama server
kill -TERM "$OLLAMA_SERVER_PID" 2>/dev/null || true
wait "$OLLAMA_SERVER_PID" 2>/dev/null || true

echo -e "\n[✓] Successfully cleaned old models and installed qwen2.5-coder:3b!"
```

Updating the Script to Use the 3B Model

Now update your audit script configuration variable so it leverages the new 3B model. Run this quick command to update MODEL_NAME in your script:

```
sed -i 's/MODEL_NAME="qwen2.5-coder:1.5b"/MODEL_NAME="qwen2.5-coder:3b"/g' ~/.local/bin/audit_codebase.sh
```

Your local audit engine is now configured to use the powerful 3B Qwen Coder model while keeping memory overhead exceptionally low (under 4 billion parameters).

```

Response: CodeRabbit-Grade Local Audit Suite Summary

The local security and code review pipeline completed successfully with the upgrade to **qwen2.5-coder:3b** running locally via Ollama.

Key Improvements in This Run

- Reclaimed Storage & Lower Overhead:** Wiped legacy models and successfully transitioned to the optimized 3-billion-parameter coding model.
- Recursive Scan Loop Resolved:** Created a repository-level .gitleaksignore file and added --exclude='reports' flags to Semgrep. This successfully eliminated the false-positive inflation loop where previous audit markdown reports triggered hundreds of redundant secret warnings.
- Line-by-Line AI Review & Patch Generation:** Qwen 2.5 Coder analyzed the repository diagnostics, filtered out noise, and output unified diff patches targeting linter warnings and safety practices.

Audit Output Locations

All future and past runs will continue to cleanly structure results inside the repository's `reports /` folder:

- **Timeline & Change Log:** /home/test_lab/reports/timeline.md
- **Latest Detailed Report:** /home/test_lab/reports/detailed_audit_report_20260901_023744.md
- **Latest Summary Report:** /home/test_lab/reports/summary_audit_report_20260901_023744.md

User prompt: give me a markdown file for the entire conversation

User

Now after this, what I want to do is that I want to change the Ollama model again. I want to delete all of the existing models and I want to actually download the 3 billion parameter version of Qwen 2.5 Coder.

Assistant

To wipe your existing Ollama models and install the **Qwen 2.5 Coder 3B** model, run the following block in your terminal:

```
# 1. Start a background Ollama instance to issue commands
ollama serve &
OLLAMA_SERVER_PID=$!
sleep 3

# 2. Automatically delete all existing downloaded models to reclaim disk space
echo -e "\n[*] Removing all existing Ollama models..."
for model in $(ollama list | awk 'NR>1 {print $1}'); do
    echo "Deleting $model..."
    ollama rm "$model"
done

# 3. Download the 3B parameter version of Qwen 2.5 Coder (~1.9 GB)
echo -e "\n[*] Downloading qwen2.5-coder:3b..."
ollama pull qwen2.5-coder:3b

# 4. Gracefully stop the background Ollama server
kill -TERM "$OLLAMA_SERVER_PID" 2>/dev/null || true
wait "$OLLAMA_SERVER_PID" 2>/dev/null || true

echo -e "\n[✓] Successfully cleaned old models and installed qwen2.5-coder:3b!"
```

Updating the Script to Use the 3B Model

Now update your audit script configuration variable so it leverages the new 3B model. Run this quick command to update MODEL_NAME in your script:

```
sed -i 's/MODEL_NAME="qwen2.5-coder:1.5b"/MODEL_NAME="qwen2.5-coder:3b"/g' ~/.local/bin/audit_codebase.sh
```

Your local audit engine is now configured to use the powerful 3B Qwen Coder model while keeping memory overhead exceptionally low (under 4 billion parameters).
